An operating nuclear power plant produces very small amounts of radioactive gases and liquids, as well as small amounts of direct radiation. If you lived within 50 miles of a nuclear power plant, you would ...

During a reaction the smaller atoms don't need as much binding energy to hold them together, so the extra energy is released as heat and radiation. In nuclear power stations, the heat caused by fission ...

High-level radioactive waste consists of irradiated, or spent, nuclear reactor fuel (fuel that is no longer useful for producing electricity). The spent reactor fuel is in a solid form, consisting of small fuel ...

Problem: Why Are People Worried About Power Generation Radiation? You've probably heard claims like "wind turbines cause cancer" or "solar panels emit dangerous rays." But wait--are these ...

The fuel used in power reactors is typically enriched in uranium-235 to levels of 3-5 percent. This isotope is capable of sustaining a controlled nuclear chain reaction that is necessary for ...

Nuclear reactors are the heart of a nuclear power plant. They contain and control nuclear chain reactions that produce heat through a physical process called fission.

Some power plants use nuclear fuel to create heat energy that is used to generate electricity, while some power plants use natural resources such as coal and other fossil fuels that ...

However, there is still extra thermal energy from the reactor vessel in the liquid-vapor mixture at the exhaust of the low pressure turbines that is not usable. This is because, as the steam loses thermal ...
